Abstract of DE10063718

A sensor (4) comprises excitation (5) and sensor (6) elements. Both are coupled to a control circuit (10), with the exciter generating mechanical vibrations that are transferred into the fluid when it reaches the sensor (1) so that the power consumption of the control circuit increases accordingly and an output signal (UA) measured using a detection circuit (R, 15) indicates the fluid level (3) has been reached.
